February 9, 2014
"Bohr and Heisenberg suggested that the thermodynamical fluctuation of temperature and energy are complementary in the same way as position and momenta in quantum mechanics."
"Finally, the question about whether or not the temperature really fluctuates should be addressed. ... If the energy fluctuates so too will any function of the energy, and that includes any estimate of the temperature."
"In this interpretation, the uncertainty $\Delta \beta$ merely reflects one’s lack of knowledge about the fixed temperature parameter $\beta$. Thus $\beta$ does not fluctuate.”

"Lavenda’s book uses these ingredients to derive the uncertainty relation $\Delta \beta \cdot \Delta U \geq 1$. Our paper observes that, on the same basis, one actually obtains a result even stronger than this, namely $\Delta \beta \cdot \Delta U = 1$."

Variances of functions of distributed quantities

Let $x$ be distributed with small variance. Consider a Taylor expandable function

$$f(x) = f(a) + (x - a)f'(a) + \frac{1}{2}(x - a)^2 f''(a) + \ldots$$

Up to second order the square of it is given by

$$f^2(x) = f^2 + 2(x - a)ff' + (x - a)^2 \left[ f'f' + ff'' \right] + \ldots$$

denoting $f(a)$ shortly by $f$. Expectation values as integrals deliver

$$\langle f \rangle = f + \frac{1}{2}\Delta x^2 f'' \quad \langle f \rangle^2 = f^2 + \Delta x^2 ff'' \quad \langle f^2 \rangle = f^2 + \Delta x^2 (f'f' + ff'')$$

Finally we obtain

$$\Delta f = |f'| \Delta x$$
One Variable EoS: $S(E)$

Product of variances

$$\Delta E \cdot \Delta \beta = 1 \quad (1)$$

Connection to the (absolute) temperature:

$$|C|\Delta T \cdot \frac{\Delta T}{T^2} = 1 \quad (2)$$

Relative variance scales like $1/\text{SQRT}$ of heat capacity!

$$\frac{\Delta T}{T} = \frac{\Delta \beta}{\beta} = \frac{1}{\sqrt{|C|}} \quad (3)$$

$C$ is proportional to the heat bath size (volume, number of degrees of freedom) in the thermodynamical limit.
Gauss distributed $\beta$ values

\[ w(\beta) = \frac{1}{\sqrt{2\pi\sigma}} e^{-\frac{(\beta - 1/T_0)^2}{2\sigma^2}} \quad (4) \]

**Expectation value**

\[ \langle \beta \rangle = \frac{1}{T_0} \]

**Variance**

\[ \Delta \beta = \sigma = \frac{1}{T_0 \sqrt{|C|}} \]
Plot Gaussian Fluctuations

Gaussian beta-distribution  $C=1:24$, inf

$w(\beta)/T$ vs $T\beta$
Superstatistics: one particle energy distribution

Canonical probability for additive thermodynamics:

\[ p_i = p(E_i) = e^{\beta(\mu - E_i)}. \]  
(5)

Characteristic function of the Gauss distribution

\[ \langle e^{-\beta \omega} \rangle = e^{-\omega/T_0} e^{\sigma^2 \omega^2 / 2}. \]  
(6)

Turning point: maximal energy until when it makes sense

\[ E_i^{\text{max}} - \mu = \omega^{\text{max}} = \frac{1}{\sigma^2 T_0} = |C| T_0. \]

Temperature, Entropy
"But unlike previous authors, Lindhard considers both the canonical and the microcanonical ensembles as well as intermediate cases, describing a small system in thermal contact with a heat bath of varying size."

"...Lindhard simply assumes that the temperature fluctuations of the total system equal those of its subsystems. This is in marked contrast with all other authors on the subject."
Subsystem - Reservoir System

The "res + sub = tot" splitting interpolates between the

*canonical* statistics for "sub" \ll "res" \approx "tot" \rightarrow \infty

and the

*microcanonical* one for "res" \ll "sub" \approx "tot" \rightarrow \infty.

In the simple $S(E)$ analysis, it is $E_{tot} = E_{sub} + E_{res}$
Mutual Info from phase space convolution

\[ \Omega(E) = \int dE_1 \, \Omega(E_1) \cdot \Omega(E - E_1). \quad (8) \]

Einstein’s postulate: \( \Omega(E) = e^{S(E)} \)

\[ e^{S(E)} = \int dE_1 \, e^{S_1(E_1) + S_2(E - E_1)}. \quad (9) \]

Normalized version:

\[ 1 = \int dE_1 \, e^{S_1(E_1) + S_2(E - E_1) - S(E)} = \int dE_1 \, e^{I(E,E_1)}. \quad (10) \]

Consider this as a probability distribution for \( E_1 \)!
Mutual Info in "sub-res" splitting

Mutual information:

\[ I(E_{\text{sub}}) = S_{\text{sub}}(E_{\text{sub}}) + S_{\text{res}}(E_{\text{tot}} - E_{\text{sub}}) - S_{\text{tot}}(E_{\text{tot}}) \]  \quad (11)

Let us denote \( E_{\text{sub}} \) by \( E \) in the followings.

\[ I'(E) = S'_{\text{sub}}(E) - S'_{\text{res}}(E_{\text{tot}} - E) = \beta_{\text{sub}} - \beta_{\text{res}} ; \]  \quad (12)

Saddle point (zeroth law):

\[ I'(E^*) = 0 \quad \Leftrightarrow \quad \beta_{\text{sub}} = \beta_{\text{res}} = \frac{1}{T^*} \]  \quad (13)
Taylor-expansion of $E - E_*$-fluctuations

for saddle point integrals with factor $e^{I(E)}$:

$$I(E) = I(E_*) + (E - E_*) I'(E_*) + \frac{1}{2} (E - E_*)^2 I''(E_*)$$  \hspace{1cm} (14)

Gaussian probability: $P(E) = e^{I(E)}$

Second derivative near equilibrium:

$$I''(E_*) = -\frac{1}{T^2_*} \left( \frac{1}{C_{sub}} + \frac{1}{C_{res}} \right) < 0$$  \hspace{1cm} (15)
Small variance approximation

Sub energy fluctuations: $\xi = E - E_*$. Temperature estimates as $T = 1/\beta$:

$$\langle 1/\beta_{\text{sub}} \rangle = \langle 1/\beta_{\text{res}} \rangle \approx T_*.$$

(16)

Energy and heat capacity are related

$$\langle E \rangle (T) = \int_0^T C(\xi) d\xi = T \cdot \bar{C}(T) \leq T \cdot C(T).$$

(17)
Gaussian E-variance in equilibrium

Energy expectation value: \[ \langle E \rangle = \overline{C}_{\text{sub}} T_* \leq C_{\text{sub}} T_* . \]

Common temperature: \[ T_* = \langle 1/\beta_{\text{sub}} \rangle = \langle 1/\beta_{\text{res}} \rangle . \]

Energy variance: \[ \Delta E^2_{\text{sub}} = \Delta E^2_{\text{res}} = C_* T_*^2 \]

with \[ C_* := \frac{C_{\text{sub}} \cdot C_{\text{res}}}{C_{\text{sub}} + C_{\text{res}}} \] (18)

Beta variance: \[ \Delta \beta_{\text{sub}} = \Delta E_{\text{sub}} / (C_{\text{sub}} T_*^2) . \]
Products of Gaussian Variances in Equilibrium

\[
\Delta \beta_{\text{sub}} \cdot \Delta E_{\text{sub}} = \frac{\Delta E_{\text{sub}}^2}{C_{\text{sub}} T^*_2} = \frac{C_*}{C_{\text{sub}}} = \frac{C_{\text{res}}}{C_{\text{sub}} + C_{\text{res}}} \leq 1. \quad (19)
\]

Using the "sub" – "res" symmetry we finally obtain:

\[
\Delta \beta_{\text{sub}} \cdot \Delta E_{\text{sub}} + \Delta \beta_{\text{res}} \cdot \Delta E_{\text{res}} = 1. \quad (20)
\]

This generalizes Landau (and many others).
Formulas with Scaled Variances

SUB:
\[ \omega_{E_{\text{sub}}}^2 := \frac{\Delta E_{\text{sub}}^2}{\langle E_{\text{sub}}^2 \rangle} \geq \frac{\Delta E_{\text{sub}}^2}{T^2 C_{\text{sub}}^2} = \frac{C_*}{C_{\text{sub}}^2} \quad (21) \]

RES:
\[ \omega_{\beta_{\text{res}}}^2 := \frac{\Delta \beta_{\text{res}}^2}{\langle \beta_{\text{res}}^2 \rangle} = \frac{\Delta E_{\text{res}}^2}{T^2 C_{\text{res}}^2} = \frac{C_*}{C_{\text{res}}^2} \quad (22) \]

For SUB + RES we finally obtain:
\[ C_{\text{sub}} \omega_{E_{\text{sub}}}^2 + C_{\text{res}} \omega_{\beta_{\text{res}}}^2 \geq 1. \quad (23) \]

This resembles Lindhard’s (Wilk’s,....) formula.
Deficiencies of the Gauss picture

1. $w(\beta) > 0$ for $\beta < 0$ (finite probability for negative temperature)

2. $\langle e^{-\beta \omega} \rangle$ is not integrable in $\omega$ (it cannot be a canonical one-particle spectrum)
Beyond Gauss: Euler

Euler-Gamma distribution

\[ w(\beta) = \frac{a^v}{\Gamma(v)} \beta^{v-1} e^{-a\beta}. \]  

Mean: \( \langle \beta \rangle = \frac{v}{a} \), variance: \( \frac{\Delta \beta}{\langle \beta \rangle} = \frac{1}{\sqrt{v}} \)

Characteristic function

\[ \langle e^{-\beta \omega} \rangle = \left(1 + \frac{\omega}{a} \right)^{-v}. \]
Euler adjusted to Gauss

Mean: $\langle \beta \rangle = \frac{v}{a} = \frac{1}{T}$, variance: $\frac{\Delta \beta}{\langle \beta \rangle} = \frac{1}{\sqrt{v}} = \frac{\Delta T}{T} = \frac{1}{\sqrt{|C|}}$

Adjusted Euler-Gamma distribution

$$w(\beta) = \frac{(|C| T)^{|C|}}{\Gamma(|C|)} \beta^{-|C|-1} e^{-|C| T \beta}.$$ (26)

Characteristic function

$$\langle e^{-\beta \omega} \rangle = \left(1 + \frac{\omega}{|C| T}\right)^{-|C|} \rightarrow \frac{e^{-\omega/T}}{|C| \rightarrow \infty}.$$ (27)
Plot Eulerian Fluctuations

Biró, Barnaföldi, Ván

Temperature, Entropy
Euler for ideal gas

Distribution of the kinetic energy sum (non-relativistic):

\[ P(E) = \prod_{j=1}^{3N} dp_j \, w(p_j) \, \delta \left( E - \sum_{i=1}^{3N} \frac{p_i^2}{2m} \right). \]  \hspace{1cm} (28)

with Gaussian (Maxwell-Boltzmann) distribution of the individual \( p_i \) components:

\[ w(p) = \frac{\sqrt{\beta}}{\sqrt{2\pi} m} \, e^{-\frac{\beta p^2}{2m}}. \]  \hspace{1cm} (29)
Euler for $E$ and $\beta$

Fourier expanding the Dirac-delta we carry out the same integral $3N$ times:

$$P(E) \, dE = \frac{1}{\Gamma\left(\frac{3}{2}N\right)} \beta E^{\frac{3}{2}N-1} e^{-\beta E} \, d(\beta E). \quad (30)$$

This is an Euler-Gamma distribution of $\beta$ for fix $E$.

... and a Poissonian for $N$ for fix $\beta E$

With $C = 3N/2$ heat capacity, we have $\langle E \rangle = CT$ and

$$\frac{\Delta E}{\langle E \rangle} = \frac{\Delta \beta}{\langle \beta \rangle} = \frac{\Delta T}{\langle T \rangle} = \frac{1}{\sqrt{C}}.$$
Product of Variances for Euler

Since

\[
\frac{\Delta E}{\langle E \rangle} = \frac{\Delta \beta}{\langle \beta \rangle} = \frac{1}{\sqrt{C}}
\]

and

\[
\langle E \rangle \cdot \langle \beta \rangle = C,
\]

We derive

\[
\frac{\Delta E}{\langle E \rangle} \cdot \frac{\Delta \beta}{\langle \beta \rangle} = \frac{1}{\sqrt{C}} \cdot \frac{1}{\sqrt{C}} = \frac{1}{C}, \quad \frac{\Delta E \cdot \Delta \beta}{C} = \frac{1}{C}, \quad (31)
\]

\[
\Delta E \cdot \Delta \beta = 1
\]
Product of Variances for Scaling Fluctuations

For scaling fluct-s, i.e. $P(E) = \beta f(\beta E)$ and $w(\beta) = Ef(E\beta)$ with the same function $f(x)$

$$\langle E \rangle = T \int xf(x)dx = CT, \quad \langle \beta \rangle = \frac{1}{E} \int xf(x)dx = C/E.$$  \hspace{1cm} (32)

It is easy to obtain also that

$$\Delta E^2 = T^2 \Delta x^2, \quad \Delta \beta^2 = \frac{1}{E^2} \Delta x^2.$$ \hspace{1cm} (33)

Conclusion:

$$\frac{\Delta E}{\langle E \rangle} \text{ fix } \beta = \frac{\Delta \beta}{\langle \beta \rangle} \text{ fix } E = \frac{\Delta T}{\langle T \rangle} \text{ fix } E = \frac{\Delta x}{\langle x \rangle}$$
Outline

1. Temperature and Energy Fluctuations

2. Finite Heat Bath Effects
   - Generalized Zeroth Law

3. Entropy formulas from zero mutual Information
Thermodynamical Temperature

Thermal exchange of energy $\rightarrow$ equality of temperature

$S(E) = \max$, while $E = E_1 \oplus E_2, \quad S = S_1(E_1) \oplus S_2(E_2)$. 

In general:

$$dS = \frac{\partial S}{\partial S_1} S'_1(E_1) dE_1 + \frac{\partial S}{\partial S_2} S'_2(E_2) dE_2 = 0,$$

$$dE = \frac{\partial E}{\partial E_1} dE_1 + \frac{\partial E}{\partial E_2} dE_2 = 0. \quad \text{(34)}$$

Zero determinant solution:

$$\frac{\partial S}{\partial S_1} \frac{\partial E}{\partial E_2} S'_1(E_1) = \frac{\partial S}{\partial S_2} \frac{\partial E}{\partial E_1} S'_2(E_2)$$
Zero determinant condition: does it factorize?

Only if:

\[ L(E) = L_1(E_1) + L_2(E_2), \quad K(S) = K_1(S_1) + K_2(S_2). \]

In this case the **thermodynamic temperature** is given by

\[ \frac{1}{T} = \frac{\partial K(S)}{\partial L(E)}. \]  

(35)

Note: such rules are associative and derived as limiting cases for subdividing an arbitrary rule in *T.S.Biro EPL 84 (2008) 56003*
Example: additive composition

This is the leading term for big systems...

\[ S = S_1 + S_2, \quad K(S) = S \]
\[ E = E_1 + E_2, \quad L(E) = E \quad (36) \]

T-temperature:

\[ \frac{1}{T} = S'(E) \]
Example: slightly non-additive composition

This includes subleading terms...

\[ S = S_1 + S_2 + aS_1 S_2, \quad K(S) = \frac{1}{a} \ln (1 + aS) \]

\[ E = E_1 + E_2 + bE_1 E_2, \quad L(E) = \frac{1}{b} \ln (1 + bE) \quad (37) \]

T-temperature:

\[ \frac{1}{T} = \frac{1 + bE}{1 + aS} S'(E) \]
Example: ideal gas

T.S. Biro, Physica A 392 (2013) 3132

Equation of state derivation for $E$-independent $C$:

$$S'(E) = \frac{1}{T}, \quad S''(E) = -\frac{1}{CT^2} \tag{38}$$

Integrations

$$-\frac{S''(E)}{S'(E)^2} = \frac{1}{C}, \quad \frac{1}{S'(E)} = \frac{E}{C} + T_0,$$

$$S(E) = C \ln \left(1 + \frac{E}{CT_0}\right), \tag{39}$$

with $S(0) = 0$. 
Example: ideal gas

There is **mutual information**:

\[
I = S(E_1) + S(E_2) - S(E)
\]

\[
= C_1 \ln \left(1 + \frac{E_1}{C_1 T_0}\right) + C_2 \ln \left(1 + \frac{E_2}{C_2 T_0}\right) - C \ln \left(1 + \frac{E}{C T_0}\right)
\]

Superstatistical and Rényi interpretation with

\[
-\ln p_i = - \ln \langle e^{-\beta E_i} \rangle = C_i \ln \left(1 + \frac{E_i}{C_i T_0}\right) = S(E_i)
\]

we obtain

\[
I = \ln \frac{p}{p_1 p_2}.
\]
Outline

1. Temperature and Energy Fluctuations
2. Finite Heat Bath Effects
3. Entropy formulas from zero mutual Information
   - q-entropy for ideal gas
   - Universal Thermostat Independence principle
Example: ideal gas

T.S. Biro, Physica A 392 (2013) 3132

$I_S \neq 0$ for additive energy $E = E_1 + E_2$.

What is another entropy, $K(S)$, for $I_{K(S)} = 0$ (i.e. $K(S)$ additive)?

Answer: $K(S) = \lambda E + \mu$; with $K(0) = 0$ and $K'(0) = 1$ the unique formula is

$$K(S) = C \left( e^{S/C} - 1 \right) \quad (42)$$
Example: ideal gas

Several subsystems: 
\[ K_N(S) = \sum_i K_i(S_i) \]

Several repeated subsystems \( \sim \) ensemble: 
\[ K_{\sum N_i}(S) = \sum_i N_i K_i(S_i). \]

Probability interpretation: 
\[ N_i = N p_i, \quad N = \sum_i N_i; \quad \sum_i p_i = 1 \]

\[ K(S) = \sum_i p_i K_i(-\ln p_i) \] (43)

This generalizes the Boltzmann-Gibbs-Planck-Shannon formula.
Entropy formulas

\[ q = 1 - 1/C; \quad C = 1/(1 - q) \]

Entropy formula for \( S \) additive:

\[ S = \sum p_i (-\ln p_i), \quad (44) \]

Entropy formula for \( K(S) \) additive:

\[ K(S) = \sum p_i K(-\ln p_i) = \frac{1}{1 - q} \sum (p_i^q - p_i), \quad (45) \]

Alternative entropy formula:

\[ S = K^{-1}(K(S)) = \frac{1}{1 - q} \ln \sum p_i^q. \quad (46) \]
Formally additive (formal logarithm): \( K(S) = C \left( e^{S/C} - 1 \right) \)

Composition rule

\[
S = C \ln \left( e^{S_1/C} + e^{S_2/C} - 1 \right) = S_1 + S_2 - \frac{1}{C} S_1 S_2 + \ldots \quad (47)
\]

For \( K(0) = 0 \) and \( K'(0) = 1 \) the subleading rule is always Rényi-Tsallis-like.
Additive $E$, $K(S)$ (non-additive $S$)

Maximal q-entropy of two systems:

$$K(S(E_1)) + K(S(E - E_1)) = \max.$$  \hspace{1cm} (48)

First derivative wrsp $E_1$ is zero $\Rightarrow$

$$K'(S(E_1)) \cdot S'(E_1) = K'(S(E - E_1)) \cdot S'(E - E_1) = \beta_K$$  \hspace{1cm} (49)

Traditional *canonical* approach: $E_1 \ll E$. 
\[ S(E - E_1) = S(E) - S'(E) E_1 + \ldots \]

Effects to higher order in \( E_1 / E \) are better compensated in the following expression

\[ \beta_K = K'(S(E)) \cdot S'(E) - \left[ S'(E)^2 K''(S(E)) + S''(E) K'(S(E)) \right] E_1 + \ldots \]

if the square bracket vanishes.

This we call \textbf{Universal Thermostat Independence} - UTI - principle.
This leads to the **UTI equation**:

\[ \frac{K''(S)}{K'(S)} = - \frac{S''(E)}{S'(E)^2} = \frac{1}{C(S)}. \]  

(50)

for a general eos leading to an arbitrary \( C(S) \) relation.

At the same time the thermodynamical temperature no more coincides with the spectral temperature:

\[ \frac{1}{T} = K'(S(E)) \cdot S'(E) = \frac{\partial K(S(E))}{\partial E} = \frac{1}{T_{\text{Gibbs}}} \cdot K'(S). \]  

(51)
Example: ideal radiation

\[ E = \sigma VT^4, \quad pV = \frac{1}{3}\sigma VT^4, \quad S = \frac{4}{3}\sigma VT^3. \]

Heat capacities:

\[ C_V = 4\sigma VT^3 = 3S, \quad C_S = \sigma VT^3 = \frac{3}{4}S, \quad C_p = \infty \quad (52) \]

\( K(S) \)-formula for the e.o.s. class \( C = S/(b - 1) \):

\[ K(S) = \frac{K'(S_0)}{b} \left[ \sum_i p_i \left( \frac{-\ln p_i}{S_0} \right)^b - 1 \right] + K(S_0). \quad (53) \]
Summary

There are temperature fluctuations, they cannot be Gaussian.

Ideal gas suggests Euler-Gamma distribution and q-entropy formulas.

UTI principle generalizes the entropy formula construction procedure.

Outlook

- Need for realistic modelling of the finite heat bath in heph.
- Adiabatically expanding systems differ from constant volume systems.
- Non-extensivity must mean a finite $C$ for infinite $V$ or $N$.
- Is there a Minimal Mutual Information Principle?

Ideal Gas: Thermodynamics

Constant Heat Capacity

\[ \frac{S''}{(S')^2} = \frac{1}{C}. \]

Integrals: temperature and entropy

\[ T = \frac{1}{S'} = \frac{E}{C} + T_0, \quad S = C \ln \left( 1 + \frac{E}{CT_0} \right) + S_0. \]

Mutual info based probability

\[ \Psi(E_1) = e^{I(E_1)} \propto \left( 1 + \frac{E_1}{C_1 T_0} \right)^{C_1} \left( 1 + \frac{E - E_1}{C_2 T_0} \right)^{C_2}. \]
Ideal Gas: max prob point

\[ l'(E_1^*) = \frac{1}{T_0 + E_1^*/C_1} - \frac{1}{T_0 + (E - E_1^*)/C_2} = 0. \]

Common temperature

\[ T_* = T_0 + E_1^*/C_1 = T_0 + (E - E_1^*)/C_2 \]

Energy sharing

\[ \left( \frac{1}{C_1} + \frac{1}{C_2} \right) E_1^* = \frac{1}{C_2} E; \quad E_1^* = \frac{C_1}{C_2} E = \frac{C_1}{C_1 + C_2} E. \]
Ideal Gas: temperature and its estimators

Since

\[ 1 + \frac{E_1}{C_1 T_0} = \frac{T_1}{T_0}; \quad 1 + \frac{E - E_1}{C_2 T_0} = \frac{T_2}{T_0} \]

the temperature (estimator) distribution becomes

\[ \mathcal{P} \propto \left( \frac{T_1}{T_0} \right)^{C_1} \left( \frac{T_2}{T_0} \right)^{C_2} \]
Express the actual estimator temperatures via the common $T_*$:

$$T_1 = T_0 + \frac{E_1}{C_1} = T_0 + \frac{E^*_1}{C_1} + \frac{E_1 - E^*_1}{C_2} = T_* + \frac{E_1 - E^*_1}{C_1}$$

$$T_2 = T_* - \frac{E_1 - E^*_1}{C_2}.$$

**Difference fluctuates, weighted sum is fixed!**

$$T_1 - T_2 = (E_1 - E^*_1) \left( \frac{1}{C_1} + \frac{1}{C_2} \right) = \frac{E_1 - E^*_1}{C_*}$$

$$C_1 T_1 + C_2 T_2 = (C_1 + C_2) T_*$$
Ideal Gas: temperature distribution

It is an **Euler-Beta distribution**

\[ \mathcal{P}(T_1) \propto T_1^{C_1} \left( T_* - \frac{C_1}{C_2} (T_1 - T_*) \right)^{C_2} \]

in the scaling variable: \( x = \frac{C_1 T_1}{(C_1 + C_2) T_*} = \frac{C_* T_1}{C_2 T_*} \)

\[ \mathcal{B}(x) = \frac{\Gamma(C_1 + C_2 + 2)}{\Gamma(C_1 + 1) \Gamma(C_2 + 1)} x^{C_1} (1 - x)^{C_2} \]

Beta distribution in \( x \), binomial in \( C_1 \) at fix \( C_1 + C_2 \), etc.
Ideal Gas: limits

Huge reservoir \((C_2 \to \infty)\: \text{for} \: x = C_1 T_1 / T_*\)

\[ \lim_{C_2 \to \infty} \mathcal{B}(x) = \frac{1}{\Gamma(C_1 + 1)} x^{C_1} e^{-x}. \]

Euler-Gamma
Ideal Photon Gas: Basic Quantities

Thermodynamic quantities from parametric Equation of State

\[ E = \sigma T^4 V, \quad pV = \frac{1}{3} \sigma T^4 V \]

Gibbs equation

\[ TS = E + pV = \frac{4}{3} \sigma T^4 V \]

Entropy and Photon Number

\[ S = \frac{4}{3} \sigma T^3 V, \quad N = \chi \sigma T^3 V. \]
Ideal Photon Gas: Differentials

\[ dE = 4\sigma T^3 V dT + \sigma T^4 dV \]

\[ dp = \frac{4}{3} \sigma T^3 dT \]

\[ dS = 4\sigma T^2 V dT + \frac{4}{3} \sigma T^3 dV \]

\[ dN = 3\chi\sigma T^2 V dT + \chi\sigma T^3 dV \]
Ideal Photon Gas: Heat Capacities

BLACK BOX scenario \((V=\text{const.})\)

\[
C_V = 4\sigma T^3 V = 3S = 4\chi N, \quad \left. \frac{\Delta T}{T} \right|_V = \frac{1}{2\sqrt{\chi N}}
\]

ADIABATIC EXPANSION scenario \((S=\text{const.})\)

\[
C_S = \sigma T^3 V = \frac{1}{4} C_V, \quad \left. \frac{\Delta T}{T} \right|_S = \frac{1}{\sqrt{\chi N}}
\]

IMPOSSIBLE scenario \((p=\text{const.})\)

\[
C_p = \infty, \quad \left. \frac{\Delta T}{T} \right|_p = 0
\]
Ideal Photon Gas: Relations between Variances

Always:

\[ \frac{\Delta S}{S} = \frac{\Delta N}{N} \]

BLACK BOX \((V=\text{const.})\):

\[ \frac{\Delta V}{V} = 0 \quad \frac{\Delta N}{N} = 3 \frac{\Delta T}{T} \]

ADIABATIC \((S=\text{const.})\):

\[ \frac{\Delta V}{V} = 3 \frac{\Delta T}{T} \quad \frac{\Delta N}{N} = 0 \]

ENERGETIC \((E=\text{const.})\):

\[ \frac{\Delta V}{V} = 4 \frac{\Delta T}{T} \quad \frac{\Delta N}{N} = 7 \frac{\Delta T}{T} \]

Volume or temperature fluctuations or both?
Gorenstein, Begun, Wilk, ...
Several Variables: \[ S(E, V, N, \ldots) = S(X_i) \]

Second derivative of \( S \) wrsp extensive variables \( X_i \) constitutes a metric tensor \( g^{ij} \).

It describes the variance \( \Delta Y^i \Delta Y^j \) with \( Y \) associated intensive variables.

Its inverse tensor \( g_{ij} \) comprises the variance squares and mixed products for the \( X_i \)-s.
How to measure all this?

- Fit Euler-Gamma or cut power-law \( \Rightarrow T, C \)
- Check whether \( \Delta T / T = 1 / \sqrt{C} \)
- If two different \( C \)-s, imply "sub + res" splitting
- Check \( E \) and \( \Delta E \) by multiparticle measurements
- Vary \( T \) by \( \sqrt{s} \) and \( C \) by \( N_{\text{part}} \)
